    }
}
```

The code snippet provided to you is a pair of code before and after modifcation. Why introduce this modification? Please tell me the reason in English

The modification introduces an XML parser security hardening measure to prevent XXE (XML External Entity) attacks.

Specifically, the change adds:

```java
reader.setFeature("http://apache.org/xml/features/disallow-doctype
```

Reason for this modification:

1. **Security Vulnerability Mitigation**: The original code was vulnerable to XXE attacks, where an attacker could inject malicious XML entities that could lead to:
   - File disclosure (reading sensitive system files)
   - Server-side request forgery (SSRF)
   - Denial of service attacks
   - In some cases, remote code execution
2. **DOCTYPE Declaration Prevention**: The feature `disallow-doctype-decl`explicitly prohibits DTD (Document Type Definition) processing, which is the primary vector for XXE attacks. Without this protection, the parser would process external entities referenced in the XML.
3. **Defense-in-Depth**: This is a security best practice when parsing untrusted XML input. Since the `migrate`method accepts arbitrary XML strings as input, it could be exploited if malicious XML is provided.
4. **Updated Exception Handling**: The `catch`block now also handles `SAXException`in addition to `DocumentException`, since setting the feature can throw `SAXException`if the parser doesn't support the requested feature.

This modification follows security guidelines from OWASP and other security authorities for safe XML parsing in Java applications.
